Study of the disorientation ...

conditions of annealing (particularly the temperature), impurity content, etc. The disorientation of blocks increases as a result of application of constant stress during creep, the most intense increase in disorientation appearing in the first stage of creep. The change in disorientation with increase in deformation during creep depends to a slight extent on the applied stress and testing temperature. However, the final stage of block disorientation, occurring between the end of the first stage of creep and fracture, is identical in specimens tested within a definite range of stress and temperatures. In this range of relatively low temperatures and not very low stresses, a change in temperature and stress does not affect the final value of disorientation after fracture (outside the above range, increase in temperature and decrease in stress lead to a decrease in disorientation). The final value of the mean angle of disorientation depends on the degree of disorientation of the initial mosaic structure. The relationships involving the mean angle of disorientation in annealed aluminium and aluminium fractured in creep (in the range of temperature and stress where

Card 2/3

Study of the disorientation ...

S/126/62/013/004/018/022  
E091/E435

the mean disorientation of blocks after fracture is identical), are linear and well-defined. The above relationships apply to aluminium of various degrees of purity and to aluminium alloys. Thus, the greater the degree of disorientation of the original structure, the greater will be the disorientation of the structure at the point of fracture. S.N.Zhurkov directed the work. There are 4 figures and 2 tables.

TITLE: Block disorientation and strength of aluminium

PERIODICAL: Fizika metallov i metallovedeniye, v.13, no.5, 1962,  
718-823

TEXT: The relationship between the degree of block disorientation and strength to rupture of aluminium was investigated. The choice of a strength parameter was governed by the authors' desire to provide a criterion which, like the U.T.S., had a conventional value. It would then depend on the time during which a body was in the stressed state. This time  $\tau$  is associated with the stress to rupture  $\sigma$  and the temperature  $T$  by the exponential relationship

$$\tau = \tau_0 \exp \left[ \frac{u_0 - \gamma\sigma}{RT} \right] \quad (1)$$

where  $R$  is the gas constant and  $u_0$ ,  $\tau_0$  and  $\gamma$  are constants determining the strength properties. Heat treatment, cold

Block disorientation ...

working and alloying do not affect the values of  $u_0$  and  $\tau_0$ , and all changes in strength of the metal are determined by the coefficient  $\gamma$ , which is thus a well-defined measure of change in the mechanical properties. For this reason the authors used  $\gamma$  as the strength parameter and studied its relationship with the degree of block disorientation, which was determined by X-ray diffraction under small angles. For the investigation, aluminium foil was used, from which flat specimens in the form of a double blade were prepared. The specimens were annealed prior to testing. The tests to rupture were carried out under conditions of uniaxial tension under constant stress and temperature. The dependence of durability on stress and temperature was determined and from the results obtained the value of  $\gamma$  was calculated. It was found that there is a well-defined relationship between  $\gamma$  and the degree of block disorientation: the lower the value of  $\gamma$  the greater the degree of the latter. The quantitative relationship between  $\gamma$  and  $\epsilon_{av}$  can be expressed by

$$\gamma = \frac{B}{\epsilon_{av}}$$

AUTHOR: Zhurkov, S. N.; Betehtin, V. I.; Slutsker, A. I.

TITLE: Disorientation of unit structures and the strength of metals

SOURCE: Fizika tverdogo tela, v. 5, no. 5, 1963, 1326-1334

TOPIC TAGS: tensile strength, disorientation, Ag, Ni, Al, Cu, Zn, low-angle scattering, x-ray scattering, dislocations

ABSTRACT: The authors studied the relationship between tensile strength and degree of disorientation in certain metals: Ag, Ni, Al, Cu and Zn. The degree of disorientation was determined by low-angle scattering of x-rays. All the investigated metals exhibit a linear relationship between strength and disorientation in the structure. The role of dislocations is not altogether clear, but it would appear to reduce to a preparation of conditions for disruption to occur. Local restressing is produced, and there occur a consequent lowering of the value of the activation barrier and an acceleration of fluctuating rupture of bonds in the metal. Orig. art. has: 7 figures, 2 tables, and 8 formulas.

TITLE: Time dependence of resistance of two-phase alloys on aluminum base

SOURCE: Fizika metallov i metallovedeniye, v. 17, no. 4, 1964, 564-571

TOPIC TAGS: aluminum alloy, duraluminum, copper, magnesium, binding energy, crystal lattice

ABSTRACT: The authors studied the time dependence of the resistance of two-phase alloys of Al with Cu (4, 0.6, and 2.7%) and Al with Mg (2%) in stable and unstable states. For these experiments, the alloys were prepared using a flux of 50% NaCl + 50% KCl. All the alloys were forged hot and were subjected to a homogenizing process of annealing. After annealing, the specimens were formed to double blades 0.1 mm thick, with the length of the homogeneous deformation part of 22 mm and a width of 3 mm. The experiments were performed under conditions of uniaxial tension at constant stress and constant temperature, following the procedure of S. N. Zhurkov and T. P. Sanfirrova (DAN, SSSR, 1955, 101, 237). The results showed the time dependence of the resistance of a two-phase alloy in the stable state (after high-temperature annealing) generally followed the relation  $t = t_0 \exp\left(\frac{U_0 - U}{RT}\right)$ .

Card 1/2

ACCESSION NR: AP4034054

where  $U_0$ ,  $\tau_0$ ,  $\gamma$  are constants depending on the resistance properties of the alloy,  $\tau$  - durability,  $R$  - gas constant,  $\sigma$  - applied stress, and  $T$  - temperature. Separation of the second phase did not seem to affect the two parameters  $U_0$  and  $\tau_0$ , corresponding to the binding energy of the atoms of pure Al and the frequency of vibration of the atoms in the crystal lattice. The phenomenon of hardening was observed from the experimental data at phase separation. This is probably not due to change in the binding energy of the atoms but to a change in the third parameter  $\gamma$ . The time dependence of resistance in the metastable state did not follow the above law. The departure from this law corresponds to the instability of the alloy state. The authors thank L. I. Vasil'yev for discussion of the results. Orig. art. has: 1 formula, 6 figures, and 1 table.

TITLE: Strength of aluminum at low temperature and disorientation of blocks

SOURCE: Fizika metallov i metallovedeniye, v. 21, no. 2, 1966, 248-251

TOPIC TAGS: aluminum, x ray spectroscopy, crystal lattice, tensile strength,  
Rupture Strength

ABSTRACT: An x-ray analysis of ruptured aluminum specimens, broken at -180°C, was carried out. The study was undertaken to determine the reasons for the deviation of the experimentally determined destruction time  $\tau$  from that calculated from the relationship

$$\tau = \tau_0 e^{\left(\frac{U_0 - \gamma\sigma}{RT}\right)},$$

where  $U_0$ ,  $\tau_0$  and  $\gamma$  are characteristic constants of the material,  $\sigma$  is the applied stress, R is the gas constant, and T is the absolute temperature. The experimental procedure followed is described by A. I. Slutsker and Ye. A. Yegorov (PTE, 1959, 5, 89). The experimental results are presented graphically (see Fig. 1). It is concluded that the deviation of  $\tau$  from the theoretical expression is caused by the variation in  $\gamma$ . The variation in  $\gamma$  is believed to be caused by a disorientation of blocks in the aluminum specimens.

TITLE: Scattering of x-rays at small angles by the mosaic structure  
of metals

18

SOURCE: Fizika tverdogo tela, v. 8, no. 3, 1966, 767-773

TOPIC TAGS: x ray scattering, grain structure, metallographic examination, small angle scattering, crystal lattice distortion, crystal dislocation

ABSTRACT: With an aim at obtaining more reliable estimates of the degree of disorientation of mosaic blocks, connected with the dislocation distribution density in block boundaries, the authors derive a more rigorous expression for the angular distribution of the intensity of x-rays scattered by such blocks at small angles. The calculation is carried out for the case of intragrain double reflections

Card 1/3

L 23029-66

ACC NR: AP6009658

(i.e., both reflecting blocks belonging to a single grain), with each grain regarded as an aggregate of blocks with orientations distributed about a certain direction in the grain. The block distribution is assumed to be fairly narrow and Gaussian. The polycrystalline volume exposed to the primary x-radiation is assumed to contain a large number of randomly oriented grains. A more accurate relation is obtained between the small-angle scattering and the block-orientation distribution function. The contribution of the microscopic distortions of the crystalline lattice and of the block dimensions to the small-angle scattering is determined. A special small-angle setup with a broad x-ray beam, described elsewhere (PTE No. 6, 89, 1959) was used, and the broadening due to the microscopic distortions and to the block dimensions was measured with a standard apparatus (URS-501). The results are used to determine the parameter of the Gaussian distribution of the block orientation and the average block disorientation angle. The connection between the block disorientation and dislocation characteristics, obtained on the basis of this method, agrees with that obtained by others, so that the method employed can be used to estimate reliably the degree of disorientation of the block and can be used successfully to analyze the dislocation structure of

ABSTRACT: A study of fossil material from drill holes in the  
deposit has permitted the division of the Yerunakovskiy  
series into four stratigraphic horizons. The faunas  
of the different horizons are distinguished not only  
by their kind and quantity but also by their overall  
character. They are either abundant ("flourishing")  
or scarce ("opressed"). Five new species of pele-  
cypods have been described from the genus Anthro-  
conauta: A. khalfini from the fourth horizon Yegozov-

TITLE: Coherent inelastic interactions between high-energy pi sup minus mesons and heavy nuclei in photoemulsions [This paper was given at the 14th Annual Conference on Nuclear Spectroscopy, Tbilisi, February 1964] /  
19

SOURCE: Yadernaya fizika, v. 2, no. 6, 1965, 1049-1053

TOPIC TAGS: pi meson, heavy nucleus, inelastic interaction, pion, nuclear emulsion

ABSTRACT: The characteristics of interactions assumed to be the coherent inelastic reactions  $\pi^- + \Lambda \rightarrow \pi^+ + \pi^- + \pi^- + A$  on heavy nuclei in a photoemulsion are investigated for 17.2 Gev/c primary pion momenta. The cross-section of this process is found to be  $5.4 \pm 1.4$  mbn. Compared with the corresponding value for carbon, this indicates a dependence of the cross-section on the atomic number of the type  $A^{1/3}$  or  $A^{2/3}$ . Orig. art. has: 5 figures and 8 formulas. [Based on authors' Eng. abst.] [JPRS]

TITLE: Influence of optical pumping of metastable helium atoms on the operation of a helium-neon laser 25

SOURCE: Zhurnal prikladnoy spektroskopii, v. 4, no. 4, 1966, 302-305

TOPIC TAGS: gas laser, laser pumping, helium, neon, light excitation, metastable state, gas discharge

ABSTRACT: The authors describe an experiment aimed at demonstrating that the population inversion in He-Ne lasers is brought about by transferring the excitation energy from the metastable  $2^3S$  helium atoms to the neon atoms in s-state. To this end, the population of the upper helium levels was reduced by optically pumping such a laser (lines 11523 and 11614 Å) with light from a helium discharge (20 mA, 2 mm Hg). The decrease in laser power due to the application of the pump pulse was determined by producing a similar power decrease with the aid of a glass plate placed in the laser cavity. From the equality of the loss, the relations are deduced for the dependence of the relative loss on the total loss, on the field density, and on the discharge current, and for the dependence of the mean lifetime of the metastable  $2^3S$  helium atoms on the discharge current. Orig. art. has: 3 figures and 11 formulas. [02]

TITLE: Cross section of inelastic processes in a helium-neon laser 25

SOURCE: Optika i spektroskopiya, v. 20, no. 6, 1966, 1078-1080

TOPIC TAGS: optic pumping, gas laser, helium neon laser, inelastic interaction,  
~~METASTABLE STATE, HELIUM, NEON~~

ABSTRACT: Optical pumping as a means of varying the populations of metastable levels of a helium-neon laser is studied. Decrease in the density of the metastable states of helium varies the populations of those neon levels which are excited by collisions with the metastable helium atoms. By measuring the variation in the amplification of the laser and the variation in the density of the metastable helium atoms, the cross section of inelastic processes can be determined. The equipment used to make the measurements is shown in a diagram. The He-Ne laser operates at the wavelengths 1.1523 and 1.1614  $\mu$ . The measurements were made on a calibrated attenuator in the form of a plane parallel glass plate inserted in the resonator to determine the generation threshold. The variation in the concentration of metastable helium atoms under the action of a helium lamp was measured from the helium absorption line 3889 Å. Results of

TITLE: Use of optical pumping for the investigation of disintegration of neon levels

SOURCE: Optika i spektroskopiya, v. 21, no. 5, 1966, 654-656

TOPIC TAGS: neon, metastable state, spectral line, pressure effect, line intensity, optic transition, optic pumping

ABSTRACT: To check on the possible decrease in the effective lifetime of neon levels with increasing pressures and on the presence of a nonradiative process of disintegration of the 2p levels of neon, the authors investigated the mechanism of the disintegration of these levels by means of optical pumping, using a procedure employed successfully before for helium (Opt. i spektr. v. 20, 734, 1965). The procedure is based on maintaining a constant concentration of metastable atoms at the investigated levels, so that the pressure dependence of the lifetime can be obtained at constant intensity. The apparatus and the test procedure are described briefly. In the experiments, the light source was pumped with a neon lamp modulated at 1000 cps, and the integral change in the intensity of the lines from the 2p levels was determined with a vacuum photocell and auxiliary equipment. The line intensities remained constant in a pressure range 0.5 - 10 mm Hg. It is therefore concluded that at these pressures there is either no nonradiative disintegration at all, or that its role is negligible. The neon atoms in

Card 1/2

UDC: 621.375.9; 535

ACC NR: AP7000037

the 2p states are disintegrated essentially by spontaneous transitions to the lower 1s levels. It is noted in the conclusion that this procedure can be useful to determine disintegration of levels connected with the metastable state by optically allowed transitions, and in other gases in which optical pumping from the metastable state is sufficiently effective. Orig. art. has: 2 figures and 2 formulas. [02]

Title : Trigger Feeding of a Couple of Geiger-Muller Counters

Orig Pub : Kokl. Bolg. AN, 1958, 11, No 5, 363-366

Abstract : A method is proposed for connecting two Geiger-Muller counters in such a way as to reduce considerably the depth time of the system. The filaments of both G-M counters are connected to anodes of the tubes of the multivibrator with two stable states. On the cathodes of the counters is applied a negative potential. The parameters of the circuits are chosen to satisfy the condition that the voltage on the counter, connected to the anode of the cut-off tube of the multivibrator, lies within the Geiger region, whereas the voltage on the counter connected to the anode

Betey, B.

✓ Delayed pulses in halogen counters. T. Ruskov and B.

~~Betey. Compt. rend. accad. bulgare sci. 12, 399-402 (1959)~~  
(in English).—In low-voltage halogen counters the pulse developed by ionizing radiation is not delayed but develops slowly, requiring 3-7  $\mu$ sec. in the interval 450-385 v. This rise time was found by using cosmic radiation to trigger a telescope of 2 high-voltage Geiger-Müller tubes and a halogen counter; the radiation triggering an accurate saw-tooth sweep pulse of an oscilloscope providing the time base on which to view the halogen pulse rise time. The use of a delayed coincidence circuit confirmed these results. The probability of the formation of neg. ions in the low-voltage halogen counter is small. At a rated voltage of 400 v., low-voltage halogen counters can successfully be used in coincidence circuits with a resolving time of  $5 \times 10^{-7}$  sec. if the threshold of the recording device is below 0.6 v.

TITLE: Properties of halogen counters with artificial extinction of discharge

PERIODICAL: Referativnyy zhurnal, Avtomatika i radioelektronika, no. 2, 1962, abstract 2-3-69s (Izv. Fiz. in-t s ANB, 1960, 8, 79-90)

TEXT: The results of experimental investigations, carried out with an arrangement permitting measurement of the dead time of the type CTC-5 (STS-5) counter (C) and for determining the probability of a pulse appearing during time  $t$  after a given pulse had been displayed. The discharge of C was terminated by means of a single-shot multivibrator, the anode of one triode being connected to the C anode through a 640 pF capacitor. The multivibrator could be controlled so as to produce the quenching pulses of varying durations and amplitudes; the restoring time of the multivibrator was determined by a network with  $RC = 3$  microseconds. The experiments have

Card 1/2

Properties of halogen ...

S/194/62/000/002/036/096  
D201/D301

shown that the dead time of C might be reduced to ~10 microseconds which differs little both from that of the multivibrator and the average lifetime of negative ions (~8.7  $\mu$ sec.). The curves of

$N_C/N_C^0 = f(t)$  are given for various amplitudes of the quenching pulse and of the C supply voltages. At large voltages, e.g. 400 V, the curves exhibit a maximum for values of t equal to 30 - 60  $\mu$ sec, owing to the formation of negative ions during the discharge. This maximum decreases with the amplitude of the quenching pulse increasing from 100 to 530 V. The last value corresponds to the case when during the quenching pulse a voltage of opposite polarity is applied to C. 7 references. /<sup>7</sup> Abstracter's note: Complete translation.

TITLE: Absorption of nuclear-active cosmic-ray particles in air

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 41,  
no. 4(10), 1961, 1043-1045

TEXT: The absorption of the nuclear-active component of cosmic radiation  
in air was measured at various altitudes above sea level. Showers were  
recorded with a coincidence arrangement of counters installed in a lead  
block (Fig. 1). The muon background was measured in Budapest 8 m under-  
ground (17 m water equivalent) to secure the recording of sixfold-  
coincidences due to muons only. The sixfold coincidences were recorded by  
the pair-connected counters 5 and 7, and 6 and 8. This underground  
measurement, together with the other measurements at various altitudes,  
made it possible to obtain corrections for background to the coincidence  
measurements with nuclear-active cosmic-ray particles. Results:

Absorption of nuclear-active cosmic-...

Place of measurement	Depth, g/cm <sup>2</sup>	Coincidences per hour
Bucharest (80 m above sea level)	1009	1.00 ± 0.04
Budapest (410 m)	969	1.55 ± 0.04
Bushteni (950 m)	907	2.37 ± 0.04
Pik Stalina (2925 m)	703	13.67 ± 0.11

The absorption mean free path  $\lambda_a$  for nuclear-active particles in air was found to be  $(119 \pm 1) \text{g/cm}^2$ . From the frequency of coincidences, the authors estimated the particle mean energy to amount to 30 Bev. The authors thank Professor L. Yanoshi, Professor G. Nadzhakov, and Professor I. Auslender for their interest and advice, N. Akhababyan, I. Kh. Ionn,

TITLE: Twenty-seven-day variation in intensity of  $\mu$ -meson component of cosmic radiation during enhancement of solar activity

PERIODICAL: Referativnyy zhurnal, Astronomiya i Geodeziya, no. 3, 1962, 36, abstract 3A277 ("Izv. Fiz. in-t s ANEB", 1961, v. 9, no. 1, 121-131, Bulgarian; Russian and English summaries)

TEXT: In 1957 - 1958 during the IGY continuous measurements of  $\mu$ -meson component of cosmic radiation were carried out. For this purpose, two crossed narrow-angle counter telescopes were used which were mounted at a distance of 30° from zenith. The data of these measurements were subjected to periodic analysis for detecting the existence of a 27-day period in variations of cosmic radiation intensity. The existence of such a periodicity is proven. Intensity variations in this period correspond to inverse phase of variation in the number of sunspots on the Sun.
